Background/Introduction: Amylose is a polysaccharide made of alpha-D-glucose units, bonded to each other through alpha(1?4) glycosidic bonds. It is one of the two components of starch, making up approximately 20-30%. Amylose is less soluble in water than the other component amylopectin. Because of its tightly packed helical structure, amylose is more resistant to digestion than other starch molecules and is therefore an important form of resistant starch. Amylose Microplate Assay Kit is a sensitive assay for determining amylose content in various samples. The pure blue is produced according to the action of amylose and iodine reagent. The measurement wavelength and reference wavelength of the amylose were 630nm and 480 nm. The absorbance difference between the two wavelengths is directly proportional to the content.
